Contents

- Problem analysis
- Decomposition and Pattern Recognition
- Abstraction
- Algorithm Design and Representation
- Implementation
- Testing and Improvement

Problem Analysis

Motivation

- **Oversaturated yet Generic:** Numerous platforms offer convenient tour but lack deep personalization.
- **The "Cookie-Cutter" Experience:** Users often face repetitive suggestions, ignoring individual preferences.
- **Neglected Destinations:** Lesser-known "hidden gems" remain overshadowed by mass tourism sites.

DU LỊCH TOUR TIẾT KIỆM

Dòng tour này Vietravel hướng đến mục tiêu bất cứ Du Khách nào cũng có cơ hội đi du lịch với mức chi phí tiết kiệm nhất. Các điểm tham quan và dịch vụ chọn lọc phù hợp với ngân sách của Du Khách nhưng vẫn đảm bảo hành trình du lịch đầy đủ và thú vị.

BỘ LỌC TÌM KIẾM

Chúng tôi tìm thấy 95 chương trình tour cho quý khách

Sắp xếp theo: Ngày khởi hành gần nhất

Ngân sách: Dưới 5 triệu, Từ 5 - 10 triệu, Từ 10 - 20 triệu, Trên 20 triệu

Điểm khởi hành: Tất cả

Điểm đến: Tất cả

Thái Lan: Bangkok - Pattaya (Thưởng Thức Buffet tại Baiyoke Sky, Tặng Massage truyền thống Thái Lan [...]
Mã tour: NINHAA7314
Khởi hành: Nha Trang
Thời gian: 5N4Đ
Phương tiện: Máy bay
Ngày khởi hành: 18/12, 08/01, 18/02, 25/02, 12/0
Giá từ: 7.990.000 ₫
Xem chi tiết

Motivation

Demand for Personalization:

- 71% of consumers expect personalized interactions [[McKinsey & Company](#)].

The Rise of "Hidden Gems":

- 69% of travelers actively seek "off-the-beaten-path" destinations to avoid overcrowding [[Booking.com Travel Predictions](#)].
- 89% want to discover authentic local culture [[Amex Global Trends](#)].

Motivation

- **Our Vision:** Personalized Discovery & Cultural Promotion
- **The Solution:** A website that delivers optimal, customized experiences aligned with specific user desires.
- **The Strategy:** Leveraging AI to connect travelers with overlooked, culturally rich locations.
- **The Impact:** Promoting the sustainable development of Vietnam's culture and tourism ecosystem.
- **Scope:** Vietnam
- **Input:** User interactions (like/dislike, view time, comment)
- **Output:** Destinations matching user's preferences

Decomposition

Decomposition

- The Project is broken into small tasks:
 - **Determine input and output scope:** clear input and output help simplifying and determining the main target, as well as facilitate developing process.
 - **Forming Database:** this is the “root” of the project, because places’ information are all getting from the database, that’s why Database is a crucial and priority section.
 - **Handling cold start recommender:** solve the initial lack of data to ensure a smooth experience for new users.
 - **Handling main recommender system:** Once user data is available, generate recommendations tailored to personal preferences.

Decomposition

- The Project is broken into small tasks:
 - **UI / UX design:** build up from simple appearance while still have base function, then upgrade the UI during the process.
 - **User's Managing:** administrator should be able to manage customers' account.

Pattern recognition

Pattern recognition

- These patterns have to be clearly determined for better recommendation:
 - **Pattern of location:** include places' specific characteristics (sea, mountain, river,...)
 - **Goal:** Optimize recommendations to match specific user preferences (tags).
 - **Location Interaction Patterns:** Track metrics like Views, Likes, Dislikes, Comments.
 - **Goal:** Solve the "Cold Start" problem by suggesting popular locations based on high visibility/engagement.
 - **User Behavior Patterns:** Identify preferences through interactions (Likes, Dislikes, Time on Page).
 - **Goal:** Detect positive signals to recommend similar locations ("Content-based Filtering").

Abstraction

Abstraction

- Those mentioned patterns can clearly define project flows and eliminate unnecessary information from the database:
 - **Defining Inputs and Outputs:**
 - **Input:** User interaction behaviors (derived from behavior patterns).
 - **Output:** Accurate recommendation results.
 - **Benefit:** Provides a clear specification for implementation.
 - **Eliminate irrelevant details:** Height, weight, Entrance gate colors, specific nearby food vendors.
 - **Frontend:** Provides the main interface for user interaction.
 - **Backend:** Receives input data from the Frontend, Processes data using the Database and Recommendation Algorithms to return optimized suggestions to the user.

Algorithmic design

Algorithmic design

1. Logical Architecture

A Hybrid System that processes both explicit and implicit data.

- The system integrates User Behavioral Analytics (what they do) with Content Semantics (what the place is).
- Data Flow:
 - **Input:** User Interactions (View Time, Likes, ...) + Natural Language Search.
 - **Processing:**
 - Module A: Dynamic Rating Scorer (converts behavior to scores).
 - Module B: Intent Detection Engine (LLM-based).
 - Module C: Similarity Engine (TF-IDF + Cosine Similarity).
 - **Output:** A personalized, ranked list of sightseeing locations.

Algorithmic design

2. The AI Components & Efficiency

Module A.

- **Implicit Rating Algorithm (The "Smart" Data Collection)**
 - Instead of relying solely on manual star ratings, calculate interest based on View Time.
 - **Noise Filtering:** Interactions under 5 seconds are discarded as accidental clicks.
 - **Linear Interpolation:** View time (5s - 90s) is mapped linearly to a score of 2.5 - 4.0. ($\text{score} = 2.5 + (\text{time} - 5) / (90 - 5) * (4.0 - 2.5)$)
 - **Efficiency:** The system only updates the database if the new calculated score is higher than the existing one, minimizing database write operations.

Algorithmic design

2. The AI Components & Efficiency

Module A.

- **Explicit Rating Algorithm**
 - **Like:** Adds +4.0 to the score.
 - **Dislike:** Subtracts -5.0 (or sets the score to the minimum of 1.0).

Algorithmic design

2. The AI Components & Efficiency

Module B. Intent Detection Engine

- **Input:** Receives raw text (e.g., "I want a cheap beach trip in Da Nang").
- **Processing:** Sends a prompt to the Groq LLM to extract structured JSON.
- **Output:** Returns standardized tags:
 - Location: "Da Nang"
 - Themes: "Beach"
 - Weather: "Cool"

Algorithmic design

2. The AI Components & Efficiency

Module C. Similarity Engine

- **Vectorization (TF-IDF):** Converts place names, descriptions, and tags into mathematical vectors.
- **Content-Based Scoring:** Uses Cosine Similarity to measure the angle between the "User Requirement Vector" (derived from Module B + History from Module A) and "Place Vectors".
 - Smaller Angle → Higher Similarity → User is MORE likely to like it.
 - Bigger Angle → Lower Similarity → User is LESS likely to like it.

Algorithmic design

2. The AI Components & Efficiency

Module C. Similarity Engine

- **Hybrid Strategy:** Merges the Content Score with:
 - Collaborative Filtering (CF): "Users like you also liked this" (Item-Item Similarity).
 - Popularity: "This place is trending" (Based on total likes/ratings).
- **Final Formula:** $\text{Score} = 0.4 * \text{Content} + 0.4 * \text{CF} + 0.2 * \text{Popularity}$ (for users with history).

Algorithmic design

3. Post-Processing

- **Soft Penalty:** If a user previously Disliked a place, we multiply its score by 0.1. It pushes it to the bottom but doesn't strictly delete it (in case they change their mind). 
- **Diversity:** The algorithm ensures the top 10 results aren't all identical (e.g., 10 museums). It forces a mix of tags 

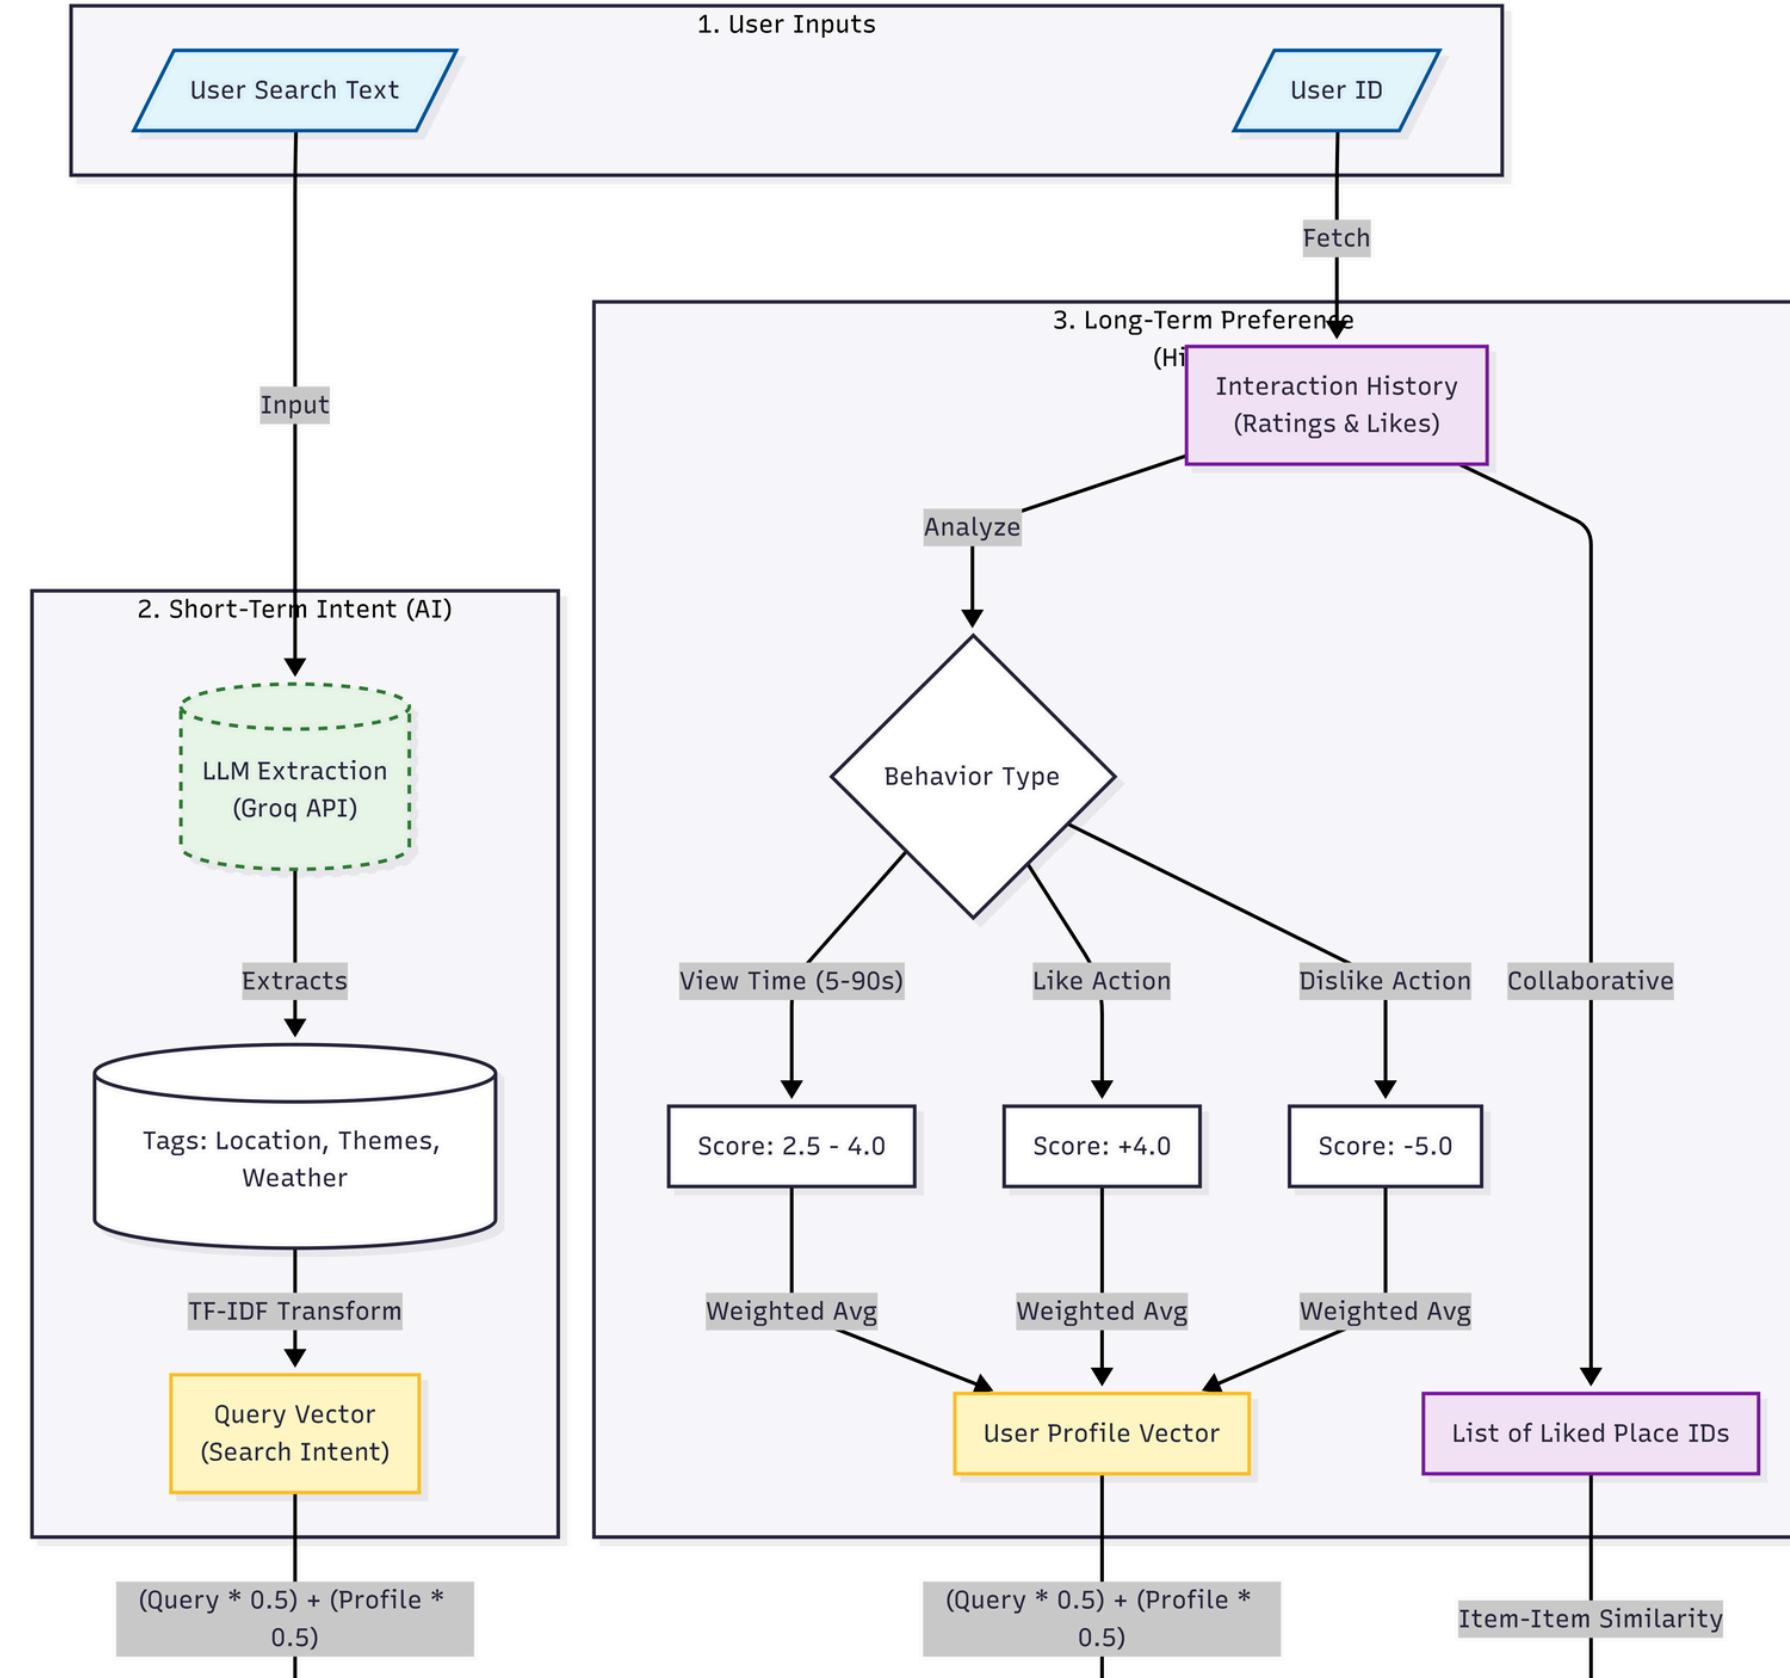

Algorithmic design

3. Post-Processing

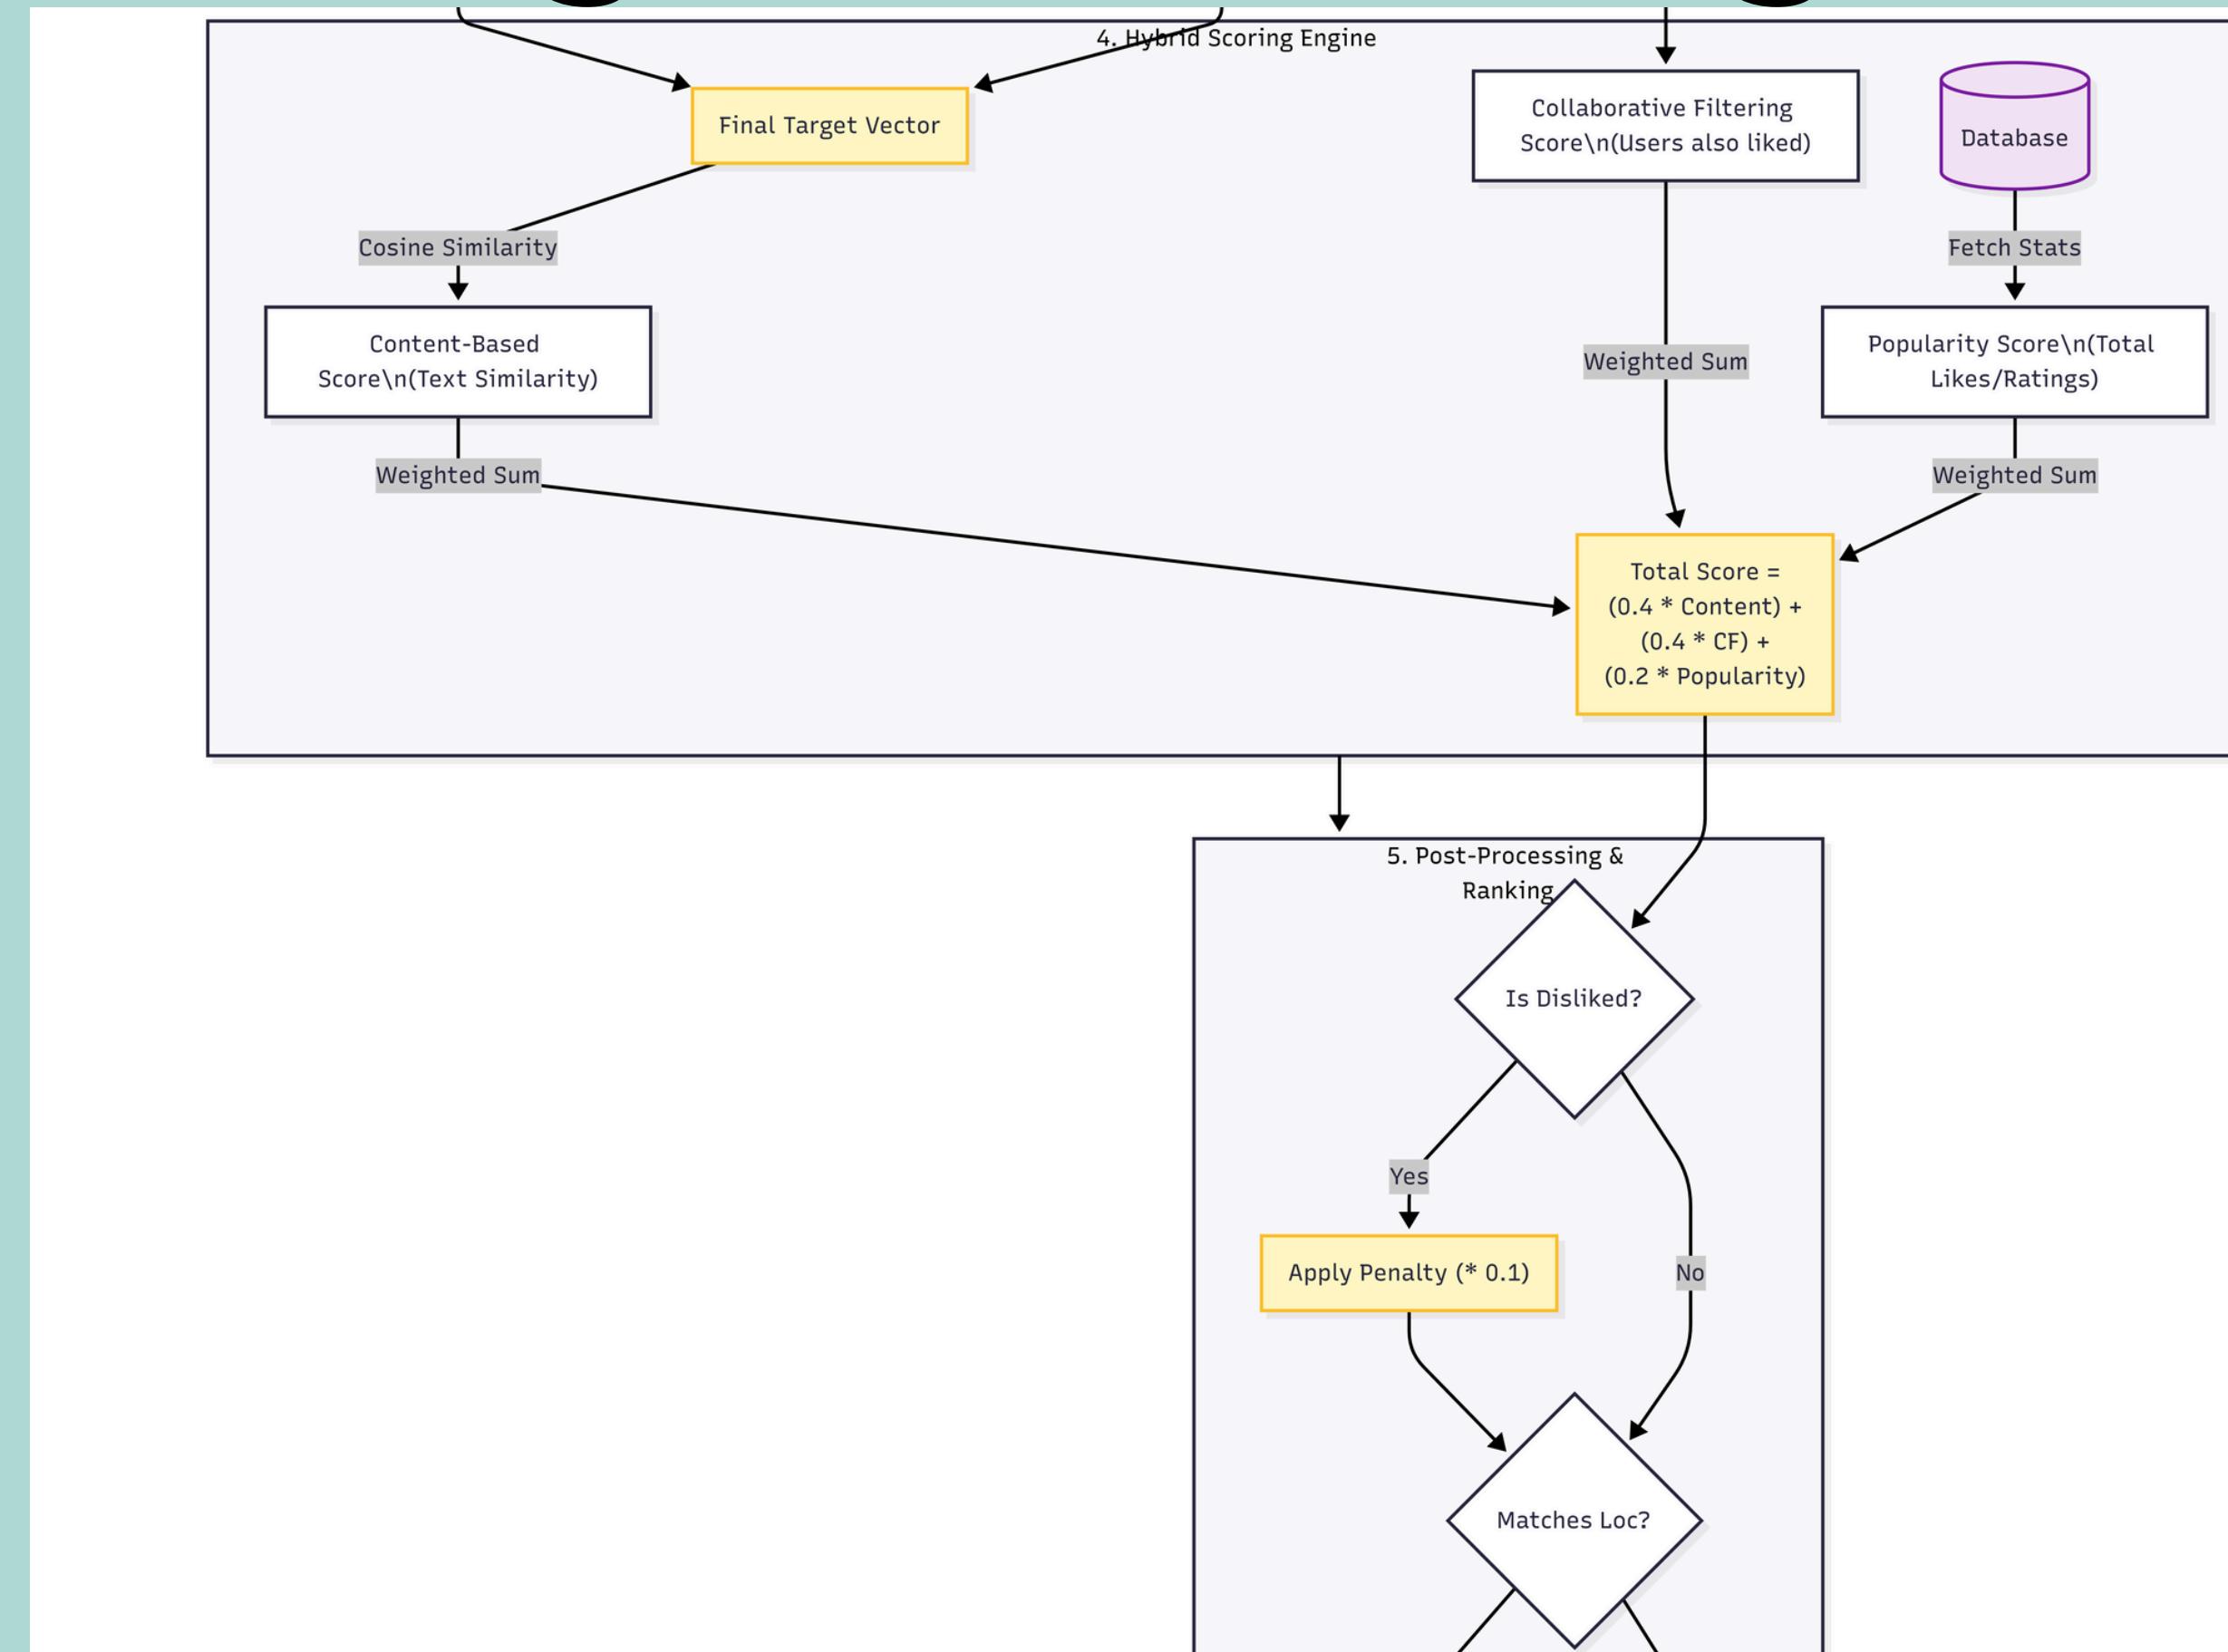

- Diverse processing:
 - **Place pool:** $\text{top_k} * 3$ (highest scoring places)
 - **From pool add if satisfied 2 limits:**
 - Maximum $\frac{1}{3}$ results from the same province
 - Maximum $\frac{1}{2}$ results from the same category
 - **After reaching 70% of pool:** add if satisfied either limit
 - **Fallback:** If still not enough items, fill remaining slots by score

Testing & Improvement

Algorithm Evaluation

1. Experimental Setup

- Total Users: 102 with various behaviors
- Methodology: Train/Test Split (80/20)

2. Overall Performance

Metric	@5	@10	@20
Precision	23.73%	17.84%	12.06%
Recall	23.94%	35.33%	47.11%
F1 Score	23.20%	23.21%	18.93%
NDCG	26.10%	30.43%	35.65%

- MAP: 19.43%
- Coverage: 65.95%
- Diversity: 30.00%

Algorithm Evaluation

3. Analysis: STRENGTHS

- **Model Validity:**
 - The model has successfully captured underlying patterns from the data.
 - Recommendations are non-random and personalized.
- **Relatively Good Recall:** 35.33% @ Top-10, 47.11% @ Top-20
 - The model successfully retrieves nearly 50% of relevant items within the top-20 results.
 - Cold-start potential: Capable of generating suggestions for new users.
- **High Coverage:** 65.95%
 - The system recommends a wide variety of items across the catalog.
 - Avoids popularity bias (does not get stuck recommending only famous locations).
- **Decent NDCG:** 26-36%
 - The ranking logic is reasonable.
 - Relevant items tend to be prioritized and appear in higher positions.

Algorithm Evaluation

3. Analysis: LIMITATIONS

- **Low Precision:** 23.73% @ Top-5
 - On average, only ~1.2 items out of the top 5 are relevant.
 - User Experience (UX) impact: Users encounter "noise" and must scroll past irrelevant items.
- **Low Diversity:** 30%
 - Recommendations lack variety.
 - Risk: The system may suggest items that are too similar to each other (e.g., suggesting 5 beaches in a row).
- **Low MAP (Mean Average Precision):** 19.43%
 - Users are forced to scroll down to find the best match.

Algorithm Evaluation

3. Analysis: Causes

- **Data Challenges:** High Tag Overlap
 - Generic tags like "sightseeing," "historical," and "nature" appear across almost all locations.
 - Consequence: The model lacks the granularity to distinguish between unique destination types.
- **Algorithmic Limitations:** Content-Based Constraints:
 - Relies strictly on static attributes (tags).
 - No Collaborative Signals: Ignores peer influence (what similar users liked).
 - Explicit only: Fails to capture implicit feedback or subtle behavioral patterns.

Algorithm Evaluation

4. Proposed improvements

- **Enrich Feature Granularity:** Introduce more specific and distinctive tags to reduce overlap.
- **Integrate Collaborative Filtering:** Incorporate user interaction patterns to enhance recommendation accuracy.
- **Enhanced preference capture:** allow users to specify price ranges or spending limits

ARRIVALS

Thank you!
